Chapter 1

Introduction

1.1 Purpose

This document represents the Requirement Analysis and Specification Document (RASD). The main goal of this document is to completely describe the system in terms of functional and non-functional requirements, analyse the real need of the customers to modelling the system, show the constraints and the limit of the software and simulate the typical use cases that will occur after the development. This document is intended to all developers and programmers who have to implement the requirements, to system analysts who want to integrate other system with this one, and could be used as a contractual basis between the customer and the developer.

1.2 Scope

The system described in this document is a taxi service for a large city. The main goals of the system are:

- simplify the access of passengers to the service
- guarantee a fair management of taxi queues

The system is composed by a web application, a mobile application and a web server.

There are three types of actors that can use the system: visitors, taxi drivers and passengers. Visitors have only two operations allowed: log in or sign in. Passengers can use both the web application and the mobile application to request a taxi. Taxi drivers use only the mobile application to:

- confirm to the system that they are going to take care of a certain request from a certain passenger
- say if they have finished a ride

- say if they want to finish their workshift.

The system, when a passenger request a taxi, informs an available taxi driver (FIFO mode) about the current position of that passenger. At this time the taxi driver has two options:

- accept : the system sends a notification to the passenger with the estimated waiting time
- reject : the system searches for another available taxi driver

The system allows also a passenger to:

- reserve a taxi by specifying the origin and the destination of the ride
- share a taxi with others, if possible, by specifying the origin and the destination of the ride. In this case the system defines the cost of the ride for each passenger.

Besides the specific user interfaces for passengers and taxi drivers, the system offers also APIs to enable the development of additional services on top of the basic one.

1.3 Definitions, acronyms and abbreviations

Definitions

- User: person that uses the service applications
- Visitor: user that has not registered nor logged in
- Registered user: user that has registered to the service
- Passenger: passenger registered to the service
- Taxi driver: taxi driver registered to the service
- System: the union of software and hardware to be developed and implemented

Acronyms

- RASD: requirements analysis and specification document
- AES: Advanced Encryption Standard
- FIFO: First In First Out
- ETA: estimated time of arrival
- API: application programming interface
- GPS: Global Positioning System

1.4 References

- Software Engineering 2 Project AA 2015/2016: Assignments 1 and 2 (RASD and DD)

1.5 Overview

This document is essentially structured in four parts:

- Introduction: it gives a description of the document and some basic information about the system. It also identifies the stakeholders and the actors involved
- Overall Description: it gives general information about the software and hardware product, constraints and assumptions
- Specific Requirements: this is the core of the document. It describes the functional and non-functional requirements combined with some scenarios. There is also a class diagram that gives an overall representation of the system
- Appendix: it provides information that is not considered part of the actual RASD. It includes: software and tools used, alloy implementation, project group organization

Chapter 2

Overall description

2.1 Product perspective

The system is composed by a web application, a mobile application and a web server. The web application runs on most common browsers, namely Chrome, Internet Explorer, Firefox, Safari. It needs a web server that supports PHP. The mobile application needs a platform supporting Android, iOS or Windows Phone. Both applications interact with a DBMS. Additional functionalities are provided through the use of APIs or interfaces, i.e. taxi reservation and the taxi sharing option.

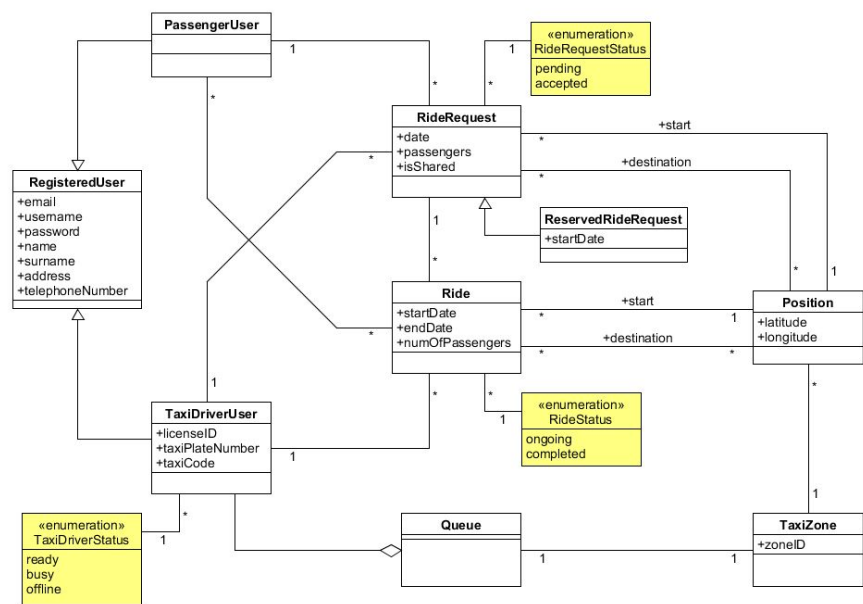

2.2 Product functions

The system allows different kinds of user to perform different actions. In particular:

- Visitors can simply register or log in, thus becoming either a passenger or a taxi driver user.
- Passengers can request, reserve and share taxi rides.
- Taxi drivers can respond (accept/refuse) to impending ride requests.

Use case diagram for *myTaxiService*

Class diagram for *myTaxiService*

2.3 User characteristics

Registered users can be either passengers or taxi drivers.

The system wants to give both an easy way to interact, thus optimizing the taxi service. To do so, passengers must be able to install and use the mobile application, or use the web application. On the contrary, taxi drivers can only install and use the mobile app; besides, their cellphone must be provided with a GPS. All users must have access to the Internet.

2.4 Constraints

2.4.1 Regulatory policies

myTaxiService is a service provided by the public company responsible for public transportation in the city. The user, who reaches this service by web or mobile application, has to agree to License Agreement rather than Privacy policy and Terms of use at registration.

The user access and use of the services constitutes his/her agreement to be bound by these Terms, which establishes a contractual relationship between him/her and myTaxiService. If user does not agree to these Terms, he/she may not access or use the services. myTaxiService may immediately terminate these Terms or any services with respect to him/her, or generally cease offering or deny access to the Services or any portion thereof, at any time for any reason. myTaxiService collects the information provided by the user, for example when creating or making changes to services on demand, through contact with customer service or during other communications. This information may include: name, email, phone number, mailing address, profile picture, payment method, products required (for service delivery), delivery receipts and other information user choose to provide. The personal data will be used only to provide the services requested.

User is responsible for obtaining the data network access necessary to use the services. User mobile network's data and messaging rates and fees may apply if he/she accesses or uses the services from a wireless-enabled device. User is responsible for acquiring and updating compatible hardware or devices necessary to access and use the service and applications and any updates thereto.

myTaxiService does not guarantee that the services, or any portion thereof, will function on any particular hardware or devices. In addition, the services may be subject to malfunctions and delays inherent in the use of the Internet and electronic communications.

2.4.2 Hardware limitations

myTaxiService defines the minimum requirements for using web and mobile applications.

- *Web application*

Supported minimum version browsers: Chrome 25, Internet Explorer 10, Firefox 20, Safari 25. Other browsers may also work
Web access at the minimum speed of 1Mbps

- *Mobile application*
Operating system: Android, iOS, Windows Phone
Memory: 512MB RAM
Hard drive: 50MB of free space
GPS navigation system (only for taxi drivers)
Web access at the minimum speed of 1Mbps

2.4.3 Interfaces to other applications

myTaxiService provides APIs to enable development of additional software on this platform.

2.4.4 Parallel operation

myTaxiService supports parallel operations cause of the nature of service. Many users can access to the service at same time thus system and database have to work with parallel requests.

2.4.5 High-order language requirements

myTaxiService requires the following high-order languages based on different platforms.

- *Web*
HTML 5 and CSS 3 standards.
- *Android*
Java 8
- *iOS*
Swift 2.0
- *Windows Phone*
C# 6.0
- *Server*
MySQL 5.6.19 and PHP 5.6.7

2.4.6 Reliability requirements

myTaxiService relies on network connections thus reliability issues are equivalent to performance issues. However, the application should not corrupt server data as a result of its actions. The system has to guarantee whole-time availability.

2.4.7 Criticality of the application

myTaxiService relies on network systems and servers. Scheduled downtime is acceptable. This system requires a generator backup and redundant power in the event of failover.

2.4.8 Safety and security considerations

myTaxiService guarantees secure communications through AES encryption algorithms.

2.5 Assumptions and dependencies

- Passenger requests a ride from web or mobile applications
- Passenger sets a correct pick-up point
- Passenger sets a correct destination
- Passenger waits the taxi driver at pick-up point
- the taxi driver uses the application in accordance with the rules of safe driving
- Taxi driver reaches the pick-up point
- Taxi driver picks up the correct passenger
- Taxi driver's phone is equipped with accessible GPS navigation system.
- Accurate taxi driver's locations are known by GPS
- Taxi driver reports correctly his availability
- The city is divided in taxi zones
- The taxi queue in a zone contains only taxi drivers available in that zone
- Service cost depends only by taxi driver
- Taxi driver confirms or denies a passenger request call
- User has access to internet

2.6 Apportioning of requirements

- Every taxi cab will be equipped with automotive navigation system implementing myTaxiService software. Personal phones are not required. This system will improve driving safety providing an easy way of interacting with the application.
- myTaxiService will implement an easy-pay system. The system calculates costs according to the route and provides payment methods with credit cards, PayPal, contact-less.

Chapter 3

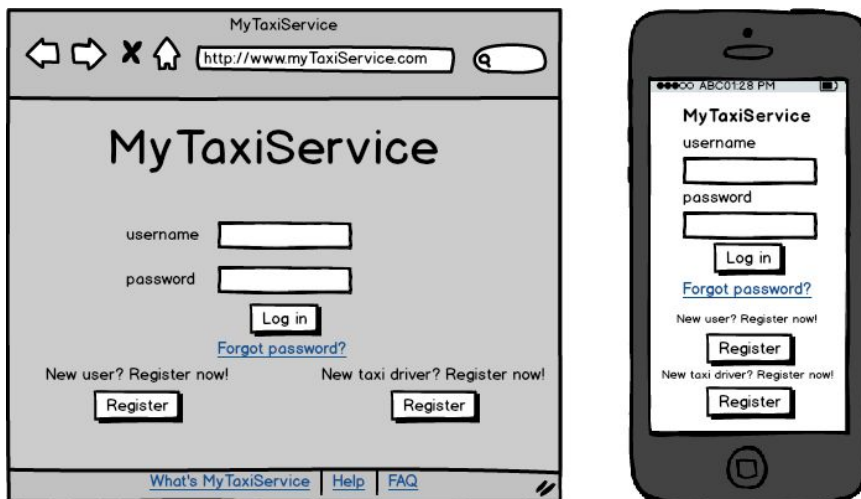

Specific requirements

3.1 External interface requirements

3.1.1 User interfaces

The interface of MyTaxiService can be both for web application and mobile application. Here will be presented some of the most important pages and screens of MyTaxiService.

Log in: In the figure below is shown MyTaxiService's homepage

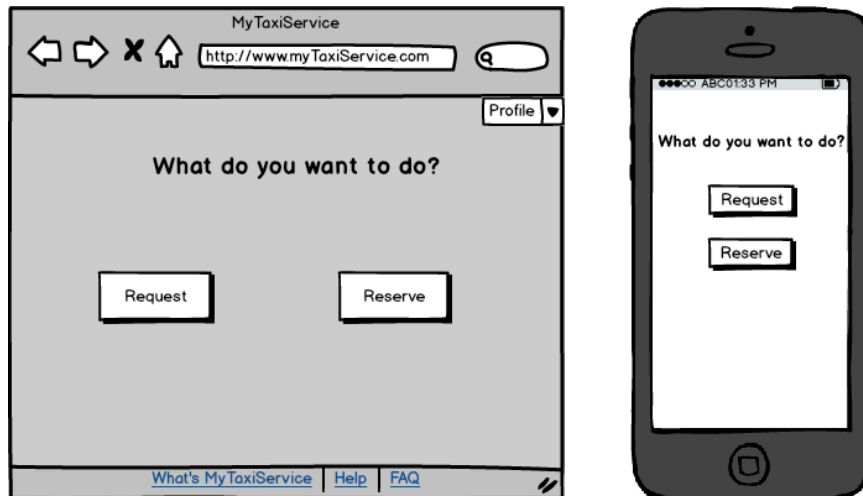

Registration passenger: View of the visitor that wants to register as a passenger

The image shows two versions of a registration form for a passenger. On the left is a desktop browser view of 'MyTaxiService' at 'http://www.myTaxiService.com/'. The form includes input fields for First Name, Surname, Username, Password, Repeat Password, and E-mail. Below these fields is a horizontal line of text, a vertical scrollbar, and a 'Confirm' button. At the bottom, there is a checkbox for 'I accept the terms & conditions' and links for 'What's MyTaxiService', 'Help', and 'FAQ'. On the right is a mobile phone view of the same form. It includes input fields for Username, Password, Repeat Password, and E-mail, followed by a 'see Terms & conditions' link, a checkbox for 'I accept the terms & conditions', and a 'Confirm' button. The mobile view also shows a status bar at the top with 'ABC01:32 PM'.

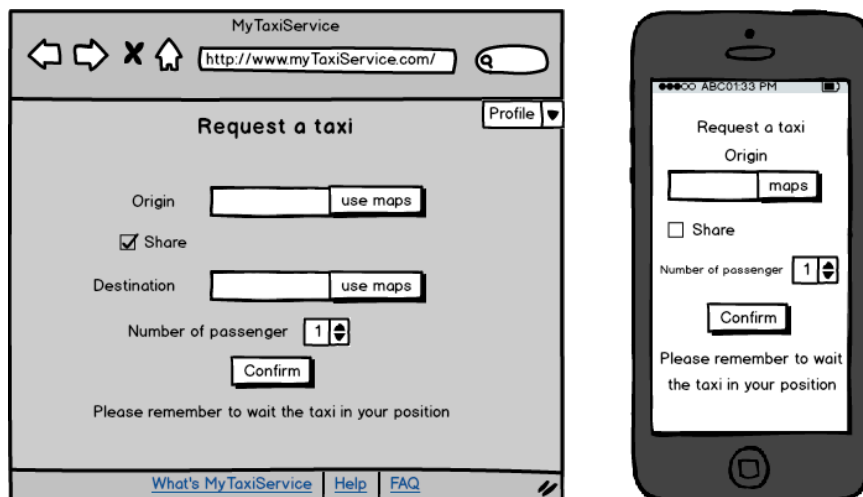

Registration taxi Driver: View of the visitor that wants to register as a taxi driver

The image shows two versions of a registration form for a taxi driver. On the left is a desktop browser view of 'MyTaxiService' at 'http://www.myTaxiService.com/'. The form includes input fields for First Name, Surname, License ID, Password, Repeat Password, and E-mail. Below these fields is a horizontal line of text, a vertical scrollbar, and a 'Confirm' button. At the bottom, there is a checkbox for 'I accept the terms & conditions' and links for 'What's MyTaxiService', 'Help', and 'FAQ'. On the right is a mobile phone view of the same form. It includes input fields for License ID, Password, Repeat Password, and E-mail, followed by a 'see Terms & conditions' link, a checkbox for 'I accept the terms & conditions', and a 'Confirm' button. The mobile view also shows a status bar at the top with 'ABC01:33 PM'.

Passenger view: View of the passenger

Request a taxi: View of the passenger when he/she requests a taxi

Reserve a taxi: View of the passenger when he/she reserves a taxi

The image shows two versions of a 'Reserve a taxi' form. On the left is a desktop browser view for 'MyTaxiService' at 'http://www.myTaxiService.com/'. It features a 'Profile' dropdown, a title 'Reserve a taxi', and input fields for 'Origin' and 'Destination', each with a 'use maps' button. The 'Time: hours/minute' section has two spinners set to 16 and 50, and a 'Share' checkbox. The 'Number of passenger' spinner is set to 1. A note states 'Remember that you can reserve a taxi 2 hours before the ride'. A 'Confirm' button is at the bottom, with links for 'What's MyTaxiService', 'Help', and 'FAQ' below it. On the right is a smartphone view of the same form, with the title 'Reserve a taxi' at the top. It includes the same input fields and controls, but the 'Share' checkbox is unchecked. The status bar at the top shows 'ABC01:34 PM'.

Taxi driver view: View of the taxi driver

The image shows a smartphone displaying a 'Taxi driver view' interface. The status bar at the top shows 'ABC01:34 PM'. The screen has a title 'What do you want to do?' and a message 'Your current status is : busy'. Below this are two buttons: 'Finish current ride' and 'Finish your workshift'.

Taxi driver notification: Notification that the taxi driver, chosen by the system, sees when a passenger request a ride.

Passenger notification : Notification that the passenger see when a taxi accept the ride

3.1.2 Hardware interfaces

myTaxiService must have access to GPS of taxi driver's phones. GPS on passenger devices is not required.

3.1.3 Software interfaces

- Database Management System (DBMS):
Name: MySQL
Version: 5.7
Source: <http://www.mysql.it/>
- Java Virtual Machine (JVM):
Name: JEE
Version: 8
Source: <http://www.oracle.com/technetwork/java/javasee/tech/index.html>
- Application server:
Name: Glassfish
Version: 4.1.1
Source: <https://glassfish.java.net/>
- myTaxiService uses Google Maps APIs in order to show to the passengers and to the taxi driver their position in the city. This API is continuously update and works for all the OS and browsers web supported by myTaxiService. More information are available on the site: <https://developers.google.com/maps/>

3.1.4 Communication interfaces

- Protocol: TCP Service: HTTPS Port : 443
- Protocol: TCP Service: HTTP Port : 80
- Protocol: TCP Service: DBMS Port : 9247

3.2 Functional requirements

3.2.1 Registration

Purpose Visitors can register to myTaxiService through the web or mobile application. They can register either as a passenger or as a taxi driver.

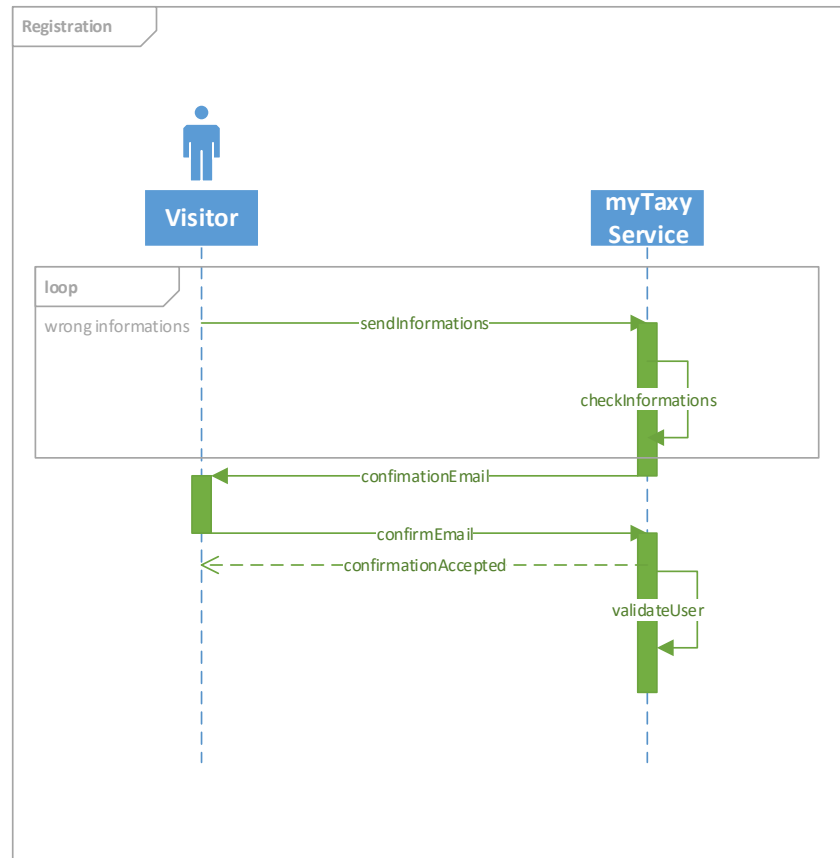

In both cases, this operation requires the visitor to fill a registration form with personal data and accept myTaxiService terms and conditions, including personal data policies, according to local law. In case of registration as a taxi driver, the system requires the visitor more info, including proof of the possession of a valid taxi driver license.

If any of the previous requirements are not met or any input is invalid, the registration fails and the system asks the visitor to repeat the process. Otherwise, a verification email is sent to the provided email address: from that email the visitor can confirm his new account and successfully end the registration process.

Scenarios

1. Alex is a student. He has heard about myTaxiService and, finding it an easy way to travel, wants to subscribe to it.
Therefore, he access to the homepage of the web application, clicks "Register", then chooses "Passenger". He fulfills the form, accepts the terms and conditions, and clicks "Confirm". However, the system cannot verify Alex's info because the confirmation password does not match with the first one. It therefore asks Alex to write it again. This time Alex fills the form correctly, then clicks "Confirm". The system verifies his info, then sends Alex a verification email to the submitted email address. Alex checks his mailbox, opens the new mail and clicks on the link inside it, redirecting him back to the web application of myTaxiService. The system informs him that the registration has successfully ended. He can now log in as a passenger user.
2. Bob is a taxi driver. His company recommends him to subscribe to myTaxiService, in order to make his work easier and improve the taxi service. Therefore, he downloads and installs the mobile app of myTaxiService on his mobile phone, then opens it. He taps "Register", then chooses "Taxi Driver". He inputs all the required data, including his driver license ID, accepts the terms and conditions and confirms. The system verifies the submitted info and sends Bob a confirmation email. Bob checks his mailbox, opens the new mail and taps on the link inside. The system informs him that the registration has successfully ended. He can now log in as a taxi driver user.

Diagrams

Sequence diagram of registration

Statechart diagram of registration

Functional Requirements

- Visitors can register either as passengers or as taxi drivers.
- Visitors can abort the registration process at any time.
- The link in the confirmation email must be clicked within 1 day, otherwise the registration is deleted along with the visitor's info.

- Registration forms contain the following info (fields):

- email address
- username
- password
- password confirmation
- name
- surname
- (*) address
- (*) telephone number
- (**) taxi license ID
- (**) taxi plate number
- (**) taxi code

All fields must be contain valid inputs.

Fields marked with (*) are not mandatory.

Fields marked with (**) are only for taxi driver registrations.

- email address and username cannot be the same as ones from other my-TaxiService users.
- password must contain at least 8 characters.
- password and password confirmation must match.

3.2.2 Login

Purpose Visitors on myTaxiService website or mobile application may access to an existing registered user account providing its corresponding username (or email address) and password. In case the submitted info do not match with any existing account info, the system notifies the visitor that the username/email address doesn't exist, or that it exists, but the submitted password is wrong.

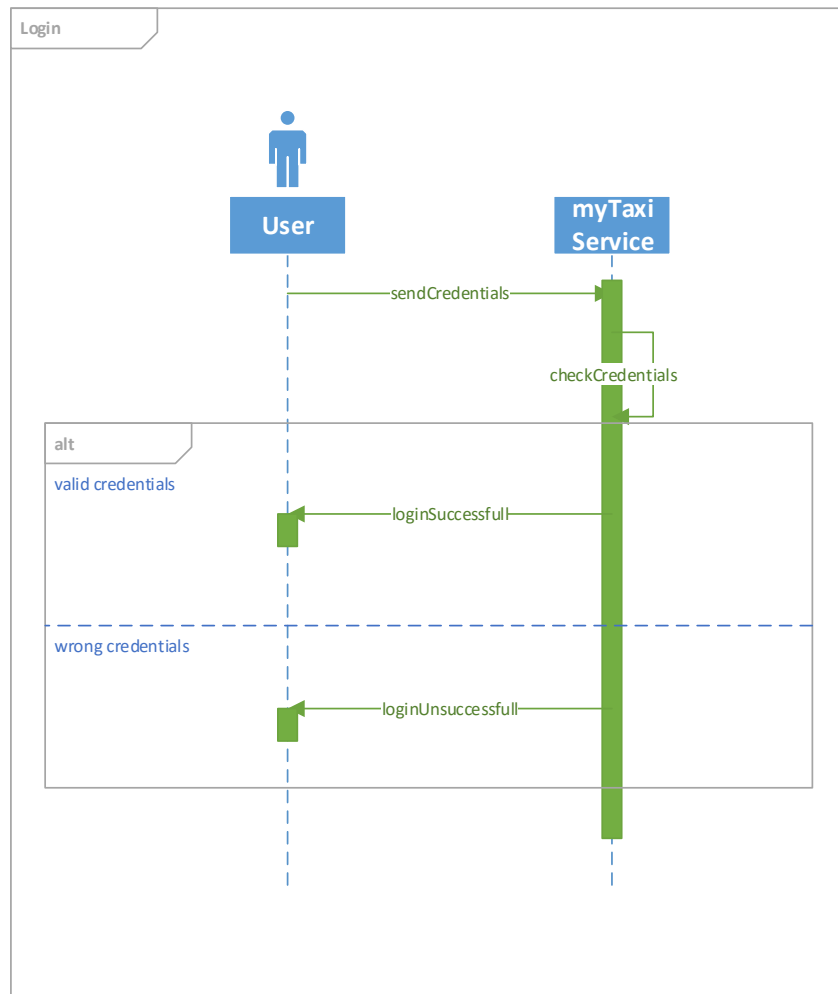

In case a user forgets his/her password, the system allows him/her to retrieve it, automatically creating a new password, setting it as the user's one and sending it to the provided email address.

Scenarios

1. Carl is a passenger user. He opens myTaxiService website, but can't remember his password to access the service. Therefore, he clicks on "Forgotten password?". The system asks him for the email address or username he provided at registration. He writes it down and clicks "Confirm". The system verifies the existence of the submitted email address, then creates a new password and sends it in an email to the submitted email address.

2. Daisy is a passenger user, familiar with the myTaxiService website. She wants to use the mobile app, too. Knowing that she can enter either username or email and password, she fills both fields and clicks on "Log in". The system verifies her info: the operation ends successfully, and she gains access to the passenger user homepage.

Diagrams

Sequence diagram of login

Statechart diagram of login

Functional Requirements

- Visitors can log in either as passengers or as taxi drivers.
- Visitors must fill the "username" field either with an existing username or with an existing email address in order to successfully log in.
- Visitors must fill the "password" field with the only password corresponding to the submitted username/email address in order to successfully log in.
- The system will ignore log in requests if at least one of the "username" and "password" fields are left blank.
- The system allows visitors to retrieve their password if they forget it, by clicking "Forgot password?".
- The system requires visitors to submit an existing email address in the "username" field in order to retrieve their password.
- The system will take care of assigning the user a new password, when he/she states to have lost the previous one.
- The system will take care of sending to the email address submitted by the visitor the new assigned password, when he/she states to have lost the previous one.
- The system allows visitors to retrieve their password once a day.

3.2.3 Standard ride request

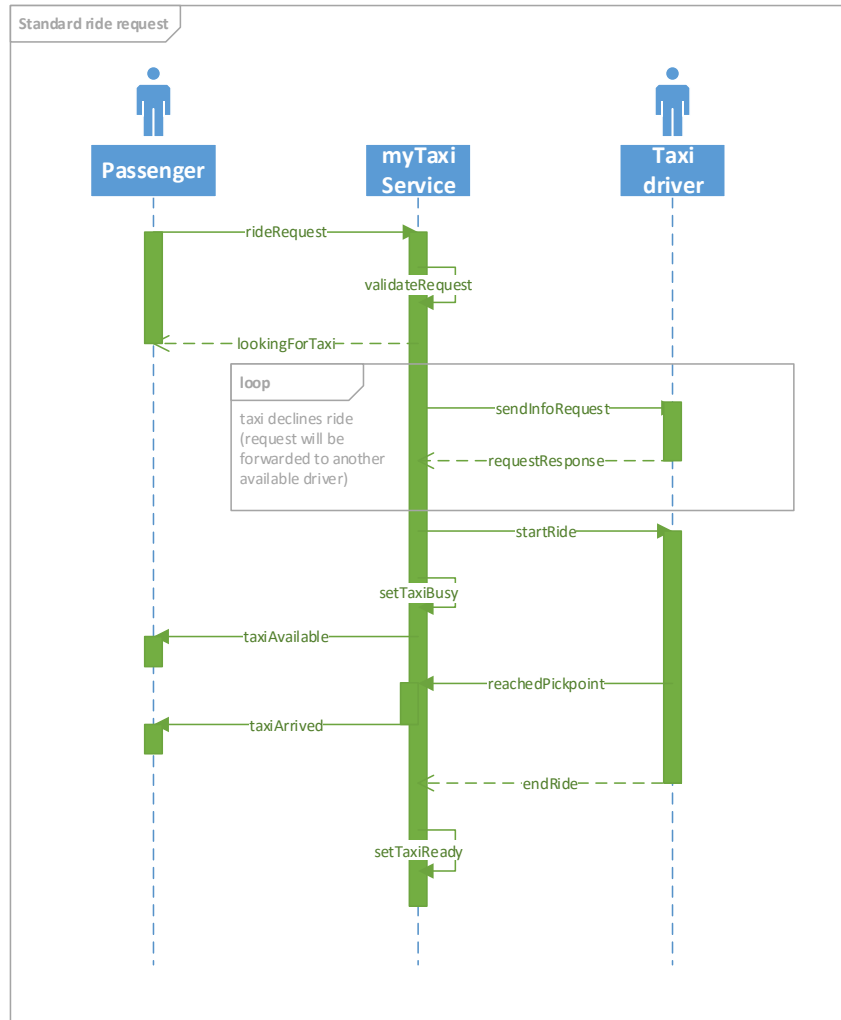

Purpose Passenger users can request a taxi both through the web or through the mobile application, giving only simple data about the number of passengers and sharing preferences (in case of shared ride, see also 3.2.5, "Shared Ride Request").

In any case, the system will then care about keeping the user informed about all details of his request, i.e. status of the request, estimated time of arrival (ETA) of the incoming taxi, in addition to its taxi code.

Scenarios

1. Elsa wanted to take the bus, but the heavy snow that fell in the last three days caused a lot of traffic problems. Fortunately for her, the taxi service is still functioning, so she opens myTaxiService on her mobile phone, logs in, and chooses "Request". She uses the GPS info to fill the "Origin" field, leaves the "Share" checkbox blank, then "Confirm". In a matter of minutes Frank, a taxi driver in her zone, accepts her request: Elsa is informed that she has to wait approximately 6 minutes for her taxi, encoded 288, to arrive. In the meanwhile, the system give her updates about the taxi position. At the expected time Frank arrives, picks Elsa up and carries her to desired destination.

Diagrams

Sequence diagram of standard ride request

Statechart diagram of standard ride request

Functional Requirements

- The system allows standard taxi ride requests to passenger users.
- The system allows standard taxi ride requests both on the web and on the mobile application.
- The system allows taxi ride requests if and only if the passenger accepts to give info about his/her location, either through GPS or directly writing down a valid location.
- The system allows taxi ride requests if and only if the passenger can be located in some definite position of some definite taxi zone.
- The system uses default values for the number of passengers and sharing preferences of a ride (1 person, no sharing), unless the passenger does specify them.
- The system uses a FIFO policy to manage forwarding of pending ride requests.
- The system uses a FIFO policy to manage the order of taxi drivers in queues to send notifications to.
- The system forwards a ride request to the first taxi driver in the considered zone queue if and only if he/she has a sufficient number of free seats available in his/her vehicle.
- The system keeps the passenger(s) notified about the status of the ride request he/she sent.
- Once a ride request has been accepted by some taxi driver, the system changes the request status from "Pending" to "Accepted".
- Once a ride request has been accepted by some taxi driver, the system calculates the ETA of the incoming taxi based on the distance between the taxi and the passenger(s), and the current traffic.
- Once a ride request has been accepted by some taxi driver, the system notifies the passenger(s) about the ETA of the incoming taxi.
- Once a ride request has been accepted by some taxi driver, the system keeps the passenger(s) notified about the current location of the incoming taxi, showing its position on a map.
- Once a ride request has been accepted by some taxi driver, the system prevents the passenger(s) to make a new ride request until the taxi driver changes the status of the ride to "Completed".

3.2.4 Reserved ride request

Purpose Passenger users can request to reserve a taxi for some definite future ride. The operation can be done both through the web or through the mobile application, and requires information about the location and exact date and time of the meeting point, the destination, the number of passengers and the sharing preferences (in case of shared ride, see also 3.2.5, "Shared Ride Request").

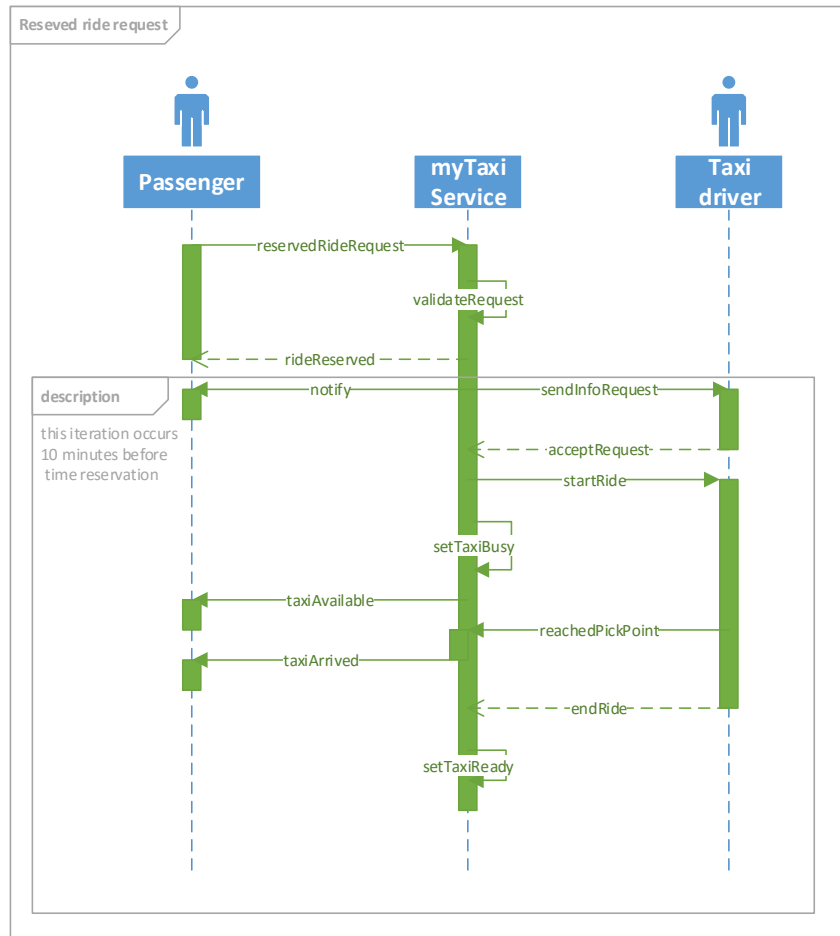

In any case, the system will take care about forwarding a taxi ride request to taxi drivers exactly 10 minutes before the agreed date and time. Reservation requests must occur at least two hours before the ride meeting time.

Scenarios

1. George has an important meeting tomorrow morning, but his car suddenly broke. He decides he will take a taxi. Therefore, he opens the homepage of myTaxiService web application on his laptop, logs in as a passenger user, then clicks "Reserve". He selects "use maps" for both position fields, and pinpoints his home and the location of the meeting as "Origin" and "Destination", respectively. He selects "7.15" as the meeting time, leaves the "Share" checkbox blank, then clicks "Confirm".

The next day, at 7.05, a reserved ride requests is received by Harry, the first taxi driver in the queue of the taxi zone where George's meeting point is located. Harry decides to refuse the request, though. The request is then forwarded to Isabelle, which was the second taxi driver in queue at the time of Harry's refusal. She accepts George's request, and at the given time arrives at his house. She picks him up and brings him to the meeting.

Diagrams

Sequence diagram of reserved ride request

Statechart diagram of reserved ride request

Functional Requirements

- The system allows reserved taxi ride requests to passenger users.

- The system allows reserved taxi ride requests both on the web and on the mobile application.
- The system allows reserved taxi ride requests if and only if the passenger gives definite existing positions of some definite existing taxi zones both for "Origin" and "Destination" fields.
- The system allows passengers to select locations either through GPS or directly writing down a valid location.
- The system allows reserved taxi ride requests if and only if the passenger gives complete info about the date and the time of the meeting.
- The system allows reserved taxi ride requests if and only if the time of the request occurs at least two hours before the ride meeting time.
- The system forwards notifications to taxi drivers about reserved taxi ride requests 10 minutes before the ride meeting time.
- The system uses default values for the number of passengers and sharing preferences of a reserved ride (1 person, no sharing), unless the passenger does specify them.
- The system uses a FIFO policy to manage forwarding of pending ride requests.
- The system uses a FIFO policy to manage the order of taxi drivers in queues to send notifications to.
- The system forwards a reserved ride request to the first taxi driver in the considered zone queue if and only if he/she has a sufficient number of free seats available in his/her vehicle.
- Once a reserved ride request has been accepted by some taxi driver, the system changes the request status from "Pending" to "Accepted".
- Once a reserved ride request has been accepted by some taxi driver, the system calculates the ETA of the incoming taxi based on the distance between the taxi and the passenger(s), and the current traffic.
- Once a reserved ride request has been accepted by some taxi driver, the system notifies the passenger(s) about the ETA of the incoming taxi.
- Once a reserved ride request has been accepted by some taxi driver, the system keeps the passenger(s) notified about the current location of the incoming taxi, showing its position on a map.
- Once a reserved ride request has been accepted by some taxi driver, the system prevents the passenger(s) to make a new ride request until the taxi driver changes the status of the ride to "Completed".

3.2.5 Shared ride request

Purpose All ride requests can be shared with other passengers, in order to divide the cost of the ride. To do so, while subscribing a ride request, passenger users may specify their preference to share the ride, besides submitting a valid destination (if not already present).

At the time of forwarding the request to taxi drivers, the system will use an appropriate algorithm to try to identify other ride requests with the same origin and a similar direction. The result will be an arrangement of those rides requests, taking into account the total number of seats necessary and calculating the optimal route to reach each destination in the least total time. The system will then proceed to forward the grouped requests as normal. In case a grouped request is not accepted, or continuously refused, for 3 minutes, the system proceeds to split the group and try to find new arrangements.

At the time of forwarding the request to taxi drivers, the system will use an appropriate algorithm to try to identify other shared ride requests with the same origin and a similar direction. The result will be an arrangement of those rides requests, taking into account the total number of seats necessary and calculating the optimal route to reach each destination in the least total time. If no request is found that matches the grouping requirements, the system may take up to 1 minute to wait for new ones. Either way, the system will then proceed to forward grouped requests as normal. In case a grouped request is not accepted, or continuously refused, for 3 minutes, the system proceeds to split the group and try to find new arrangements, in the same way described before.

When a grouped request is successfully accepted by some taxi driver, the system will take care of splitting the taxi fee among all passengers, proportionally to the distance traveled by each one.

Scenarios

- Jack and his friend Kevin want to go home after a party. They drank a bit too much, and Jack doesn't feel sober enough to drive. Therefore, he opens myTaxiService mobile application, logs in as a passenger user, and chooses "Request". Jack and Kevin don't have much money left, though, so Jack decides to share the ride. He ticks the "Share" checkbox, writes down his address as "Destination", then selects "Confirm". After a while Lara, who was at the same party and lives between Jack and her current position, sends a similar shared ride request, with destination her home. The system arrange the two requests in the same taxi. A minute after, Mark, a taxi driver, accepts the grouped request, and comes to pick up the three. He brings Lara home first, making her pay one third of the traveled distance. Then, Mark proceeds to Jack's home, and upon arrival makes Jack and Kevin pay the remaining cost of the ride. They decide to each pay half the fee.

Jack and his friend Kevin want to go home after a party. They drank a bit too much, and Jack doesn't feel sober enough to drive. Therefore, he

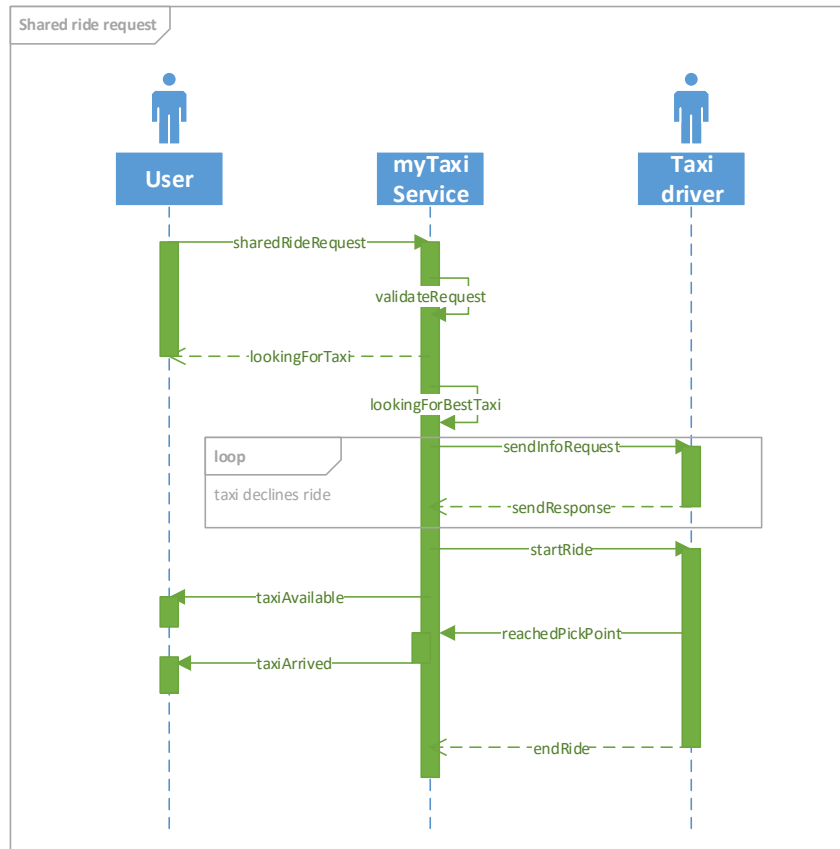

opens myTaxiService mobile application, logs in as a passenger user, and chooses "Request". Jack and Kevin don't have much money left, though, so Jack decides to share the ride. He ticks the "Share" checkbox, writes down his address as "Destination", then selects "Confirm". After less than one minute Lara, who was at the same party and lives between Jack and her current position, sends a similar shared ride request, with destination her home. The system arranges the two requests in the same taxi. Soon after, Mark, a taxi driver, accepts the grouped request, and comes to pick up the three. He brings Lara home first, making her pay one third of the traveled distance. Then, Mark proceeds to Jack's home, and upon arrival makes Jack and Kevin pay the remaining cost of the ride. They decide to each pay half the fee.

- Neil has bought a ticket to the finals of his favourite team. Considering that during the day of the match it's almost impossible to find parking near the stadium, he decides go there by taxi. On his computer, he access the homepage of myTaxiService web application, logs in as a passenger user, then clicks "Reserve". He chooses an hour before the beginning of the match as Date and Time, ticks "Share" checkbox, selects his home as "Origin" and the stadium as "Destination" from the maps, then "Confirm". The system informs him that the request is successful. The system verifies the existence of other suitable shared ride requests to group Neil's one with, but doesn't find anything.

The day of the match Oliver, another fan who lives in the same street of Neil, jumps to his same conclusion. A bit more than an hour before the match, he requests a shared ride from home to the stadium. Fortunately for him, no request was made that was eligible to be grouped with Neil's, so the system proceeds to group them. After a few minutes, Petra accepts Neil and Oliver grouped request, and comes to pick them up. Upon arrival, they split the ride fee equally.

The day of the match Oliver, another fan who lives in the same street of Neil, jumps to his same conclusion. A bit more than an hour before the match, he requests a shared ride from home to the stadium. Fortunately for him, the system finds Neil's request and proceeds to group it with his own. After a few minutes, Petra accepts Neil and Oliver grouped request, and comes to pick them up. Upon arrival, they split the ride fee equally.

Diagrams

Sequence diagram of shared ride request

Statechart diagram of shared ride request

Functional Requirements

- The system allows taxi ride sharing to passenger users.
- The system allows taxi ride sharing both on the web and on the mobile application.

- The system allows both standard shared taxi ride requests and reserved shared taxi ride requests, simply ticking the "Share" checkbox while doing any any kind of taxi ride request.
- Both kinds of shared ride requests require no less data than their non-shared forms (see also 3.2.3, "Standard ride request" and 3.2.4, "Reserved ride request").
- The system allows standard shared taxi ride requests if and only if the passenger also gives a definite existing position of some definite existing taxi zone as "Destination" (reserved taxi ride requests already require this, even if non-shared).
- The system allows passengers to select the input for "Destination" either through GPS or directly writing down a valid location.
- The system, at the time of forwarding any shared ride request, will use a special algorithm to calculate good arrangements between different shared ride requests.
- The arrangement algorithm search different shared ride requests to form a single, grouped, shared ride request.
- The arrangement algorithm considers for grouping only shared rides with close "Origin" positions and similar directions towards "Destination" positions. Similar directions means that going from the origin to the farthest destination implies passing by the other destination(s) as well.
- The arrangement algorithm also considers the total number of passengers in a taxi. Groups that would occupy too many seats are not eligible.
- The arrangement algorithm can group even standard and reserved ride requests together, as long as all the others requirements are met.
- The arrangement algorithm may take up to 1 minute to wait the reception of new shared ride requests that satisfy the grouping requirements.
- The system will consider group requests as a single one when forwarding them to taxi drivers.
- Taxi drivers can see all details of all shared requests when receiving notification of a grouped request.
- Taxi drivers can accept or refuse grouped requests as normal.
- The system will automatically split up groups of shared requests if they're continuously refused, or simply not accepted, for 3 minutes since their forwarding.
- The system will then proceed to recalculate possible groups with the special algorithm, but excluding the arrangements that were already tried.

- The system calculates how to split taxi fees equally on all passengers on a shared ride, depending on the distance traveled by each one and the number of passengers during each part of the ride.
- The system notifies the taxi driver how much of the total fee each passenger will have to pay, in percentage.

3.2.6 Request notification and response

Purpose Taxi driver users, if logged in on the myTaxiService mobile application and not busy, are able to receive notifications about pending ride requests. They then become able to respond to them, either accepting or refusing.

The system manages taxis assigning each taxi driver to the queue of his/her corresponding taxi zone. Every request notification from a certain zone is forwarded to the first eligible taxi driver of that taxi zone queue. If that first taxi driver accepts it, the request becomes accepted and the taxi driver status changes to "Busy": he/she is removed from the queue. He/she will be put back on the bottom of the queue as soon as he notifies the system that he's finished the ride and his/her status changes back to "Ready".

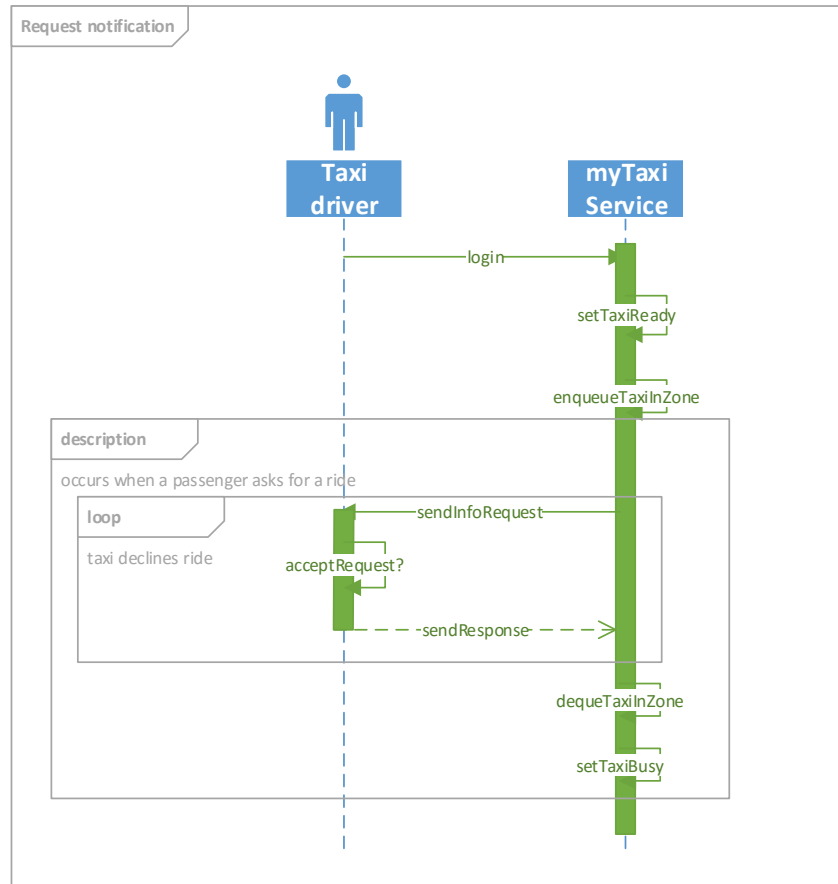

If the first taxi driver refuses instead, the request is forwarded to the second taxi driver; the same goes for the third, the fourth and so on. Either way, taxi drivers that refuse a request end on the bottom of their taxi zone queue. Finally, taxi drivers must respond to each request within one minute from its forwarding, otherwise the system will automatically take it as a refusal.

Scenarios

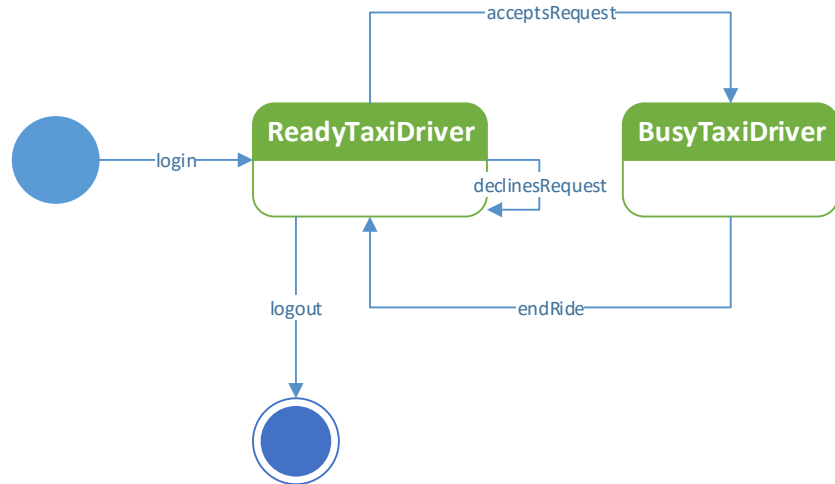

- Pamela is a taxi driver. She's a few minutes from ending her workshift before launchbreak, when suddenly a new request notification arrives on the myTaxiService application on her mobile phone. The request comes from passenger user Qasim. Pamela can see his position on the map. He's pretty far from her current position, so she decides to refuse and end her workshift. The system changes her status to "Offline". Qasim's request is instead forwarded to the next taxi driver user in the same zone queue, Rebecca. She decides to accept the request, thus changing her status from "Ready" to "Busy" and leaving the taxi zone queue. Qasim is notified that his request has been accepted. Rebecca goes to pick him up and brings him to his destination.
- Simon is a taxi driver user. It's late in the night and he's really tired: without noticing, he dozes off. Not long after, a notification arrives on his mobile phone. It's a shared request from passenger users Thomas and Ursula. Unfortunately, Simon doesn't notice it: one minute passes and the system automatically take it as a refusal. The grouped request is forwarded to taxi driver Violet, who decides to accept it: the system removes her from the queue and changes her status to "Busy". Thomas and Ursula are both notified that they're request have successfully been accepted, and

that Violet is on her way to them. Some minutes after, Violet arrives and bring them to their destination, splitting the fee according to the system indications.

Diagrams

Sequence diagram of request notification and response

Statechart diagram of request notification and response

Functional Requirements

- The system allows taxi drivers to receive ride request notifications on their mobile phone application and respond to them, either accepting or refusing.
- The system notifies taxi drivers about all request notifications forwarded to them.
- The system uses a FIFO policy to manage forwarding of pending ride requests.
- The system uses a FIFO policy to manage the order of taxi drivers in queues to send notifications to.
- The system forwards a ride request to the first taxi driver in the considered zone queue if and only if he/she has a sufficient number of free seats available in his/her vehicle.
- Taxi zone queues contain only taxi drivers that currently have status "Ready".
- Taxi zone queues contain only taxi drivers that are currently located in that taxi zone.
- Taxi ride notifications show all requesting passengers' username and position on a map.

- The system gives taxi drivers one minute to accept or refuse request notifications, otherwise take it as a refusal. This is to avoid long waiting times for passengers.
- Once a ride request has been accepted by some taxi driver, the system changes his/her status to "Busy" and he/she's removed from his/her taxi zone queue.
- The system allows taxi drivers to notify the end of the ride, when they're doing one (i.e. when they accepted a ride request).
- Once a taxi driver notifies the end of a ride, the system changes his/her status to "Ready" and he/she's put on the bottom of his/her taxi zone queue.

3.2.7 Availability settings

Purpose Taxi drivers are able to notify the system about their status through the mobile application at any moment, as long as they're logged in. In particular, the status can be either "Ready", "Busy" or "Offline".

Whenever a taxi driver logs in, the system automatically sets his/her status from "Offline" to "Ready" and put him/her on the bottom of its current taxi zone queue, based on GPS info.

When he/she accepts a taxi ride, the status is automatically updated to "Busy": the system then removes him/her from the queue, preventing the arrival of other ride requests.

Similarly, when the ride is over, the taxi driver has to notify the system that the ride has ended: the system automatically changes the status back to "Ready" and puts him/her back on the bottom of the current taxi zone queue, thus waiting for a new ride request.

Finally, when the taxi driver finishes his workshift, he may inform the system, or simply log off. In both cases, his/her status automatically switches to "Offline".

Scenarios

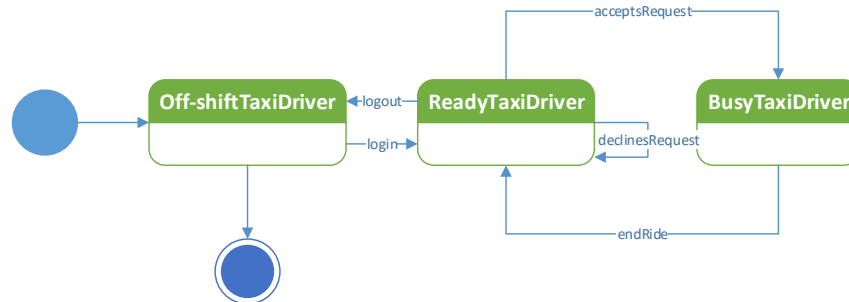

- William is a taxi driver subscribed to myTaxiService. He logs in through his mobile phone and his status changes from "Offline" to "Ready". The system receives info from the GPS and puts William on the bottom of the taxi zone he's currently in. After a while, his phone notifies him about a new ride request: it's from passenger user Xenia. William decides to accept it and his status changes to "Busy". He's no longer in the taxi queue. William goes to the start location, picks up Xenia and takes her to her destination. When they arrive, William informs the system that he has concluded the ride: his status changes to "Ready". The system puts him on the bottom of his current taxi zone queue. Later on, he receives another ride requests, but this time he decides to refuse it: its status remains unchanged as "Ready", but he loses all his positions in the

queue. A few hours later, William finishes his worktime and logs off. The system sets his status to "Offline" and removes him from any queue.

Diagrams

Sequence diagram of availability settings

Statechart diagram of availability settings

Functional Requirements

- The system uses a FIFO policy to manage taxi zone queues.
- The system uses info provided by the GPS to locate taxis and decide their respective queues.
- The system automatically inserts taxi drivers in queues when their status changes to "Ready".

- The system automatically removes taxi drivers from queues when their status changes to "Busy" or "Offline".
- The status automatically changes to "Busy" when the taxi driver accepts a ride request.
- The status automatically changes to "Ready" when the taxi driver notifies the end of a ride.
- When status is "Ready", the application notifies about ride requests.
- When status is "Ready", the application enables the taxi driver to accept/refuse requests.
- When status is "Busy", the application prevents ride requests notifications.
- When status is "Busy", the application enables the taxi driver to notify the end of the current ride.

3.2.8 Account settings

Purpose The system allows registered users to view and modify their profiles at any moment, as long as they're logged in. Usernames cannot be modified, while modified email addresses, taxi license IDs and taxi codes must not match with the ones of other users, otherwise the system denies the modification request. In case of modified email address, the system sends a confirmation email to the new address. Modification will successfully ends when the user clicks the link in the sent email.

Scenarios

- Zac uses to periodically change his account password, in order to increase protection. To do so, every 3 months, he opens myTaxiService on his mobile phone, chooses "Profile", then "Modify". He selects the password field, writes down a new one, then writes it again in the "Confirm password" field. Finally, he clicks "Confirm": the system informs him that his account password has successfully been updated.

Diagrams

Sequence diagram of account settings

Statechart diagram of account settings

Functional Requirements

- Account settings are available to both passenger and taxi driver users.
- Account settings are available both on the web and the mobile application.
- Account settings are accessible from the start screen of both apps, through the "Profile" button.
- The system allows users to view all their profile info, submitted during registration (see also 3.2.1, "Registration").
- The system allows users to modify all their profile info, submitted during registration, with the only exception of username.
- Modifying the password requires to write the old one, and the new one twice; if the former password is not correct or if the two new passwords submitted do not match, the system asks for all passwords again and notifies the user.
- Modifying the email address, the taxi license ID or the taxi code requires that the new one doesn't match with the one of another registered user.
- Modifying the email address requires confirmation through an email sent to the submitted email address.
- The system allows users to abort modifications at any time.
- The system allows users to delete their account: confirmation is required to proceed.

3.3 Performance Requirements

myTaxiService will perform 95% of the operations within 4 seconds; the total amount of the operations within 10 seconds. The system should ensure at least 2000 passengers connected and 500 taxi drivers connected.

3.4 Design constraints

myTaxiService wants to reach most of taxi drivers and passengers, requiring minimum specifications for devices. Taxi drivers, registered to the system, have to use their own devices provided with GPS navigation system to perform the service. Mobile applications have to offer backward compatibility.

3.5 Software system attributes

Reliability The mean time between failures (MTBF) shall exceed 3 months.

Availability In order to maintain the system up-to-date and secure, myTaxiServer schedules downtime periods where will be executed routine operations. The service should be available 99% of the time.

Security myTaxiService to ensure service availability and data protection use:

- AES cryptography algorithm on network operations
- Data are encrypted and stored in backup drives to prevent system failure
- Login authentication. Users, after the registration, have to confirm their e-mail with the security code sent to the e-mail write in the registration form
- SQL injection detection

Server architecture will be implemented separating data from application. Application server must be separated from database and from the web server. All architectures are divided by firewalls.

Maintainability To ensure an easy maintenance of the software, it must be well-documented and written following coding patterns.

Portability Web programming ensures a wide target of browser. Mobile applications instead, cause of different languages and devices, have to be written following coding patterns for easy portability. Availability of the service is ensured by hardware and software limitations in Section 2.4.2.

Appendix A

Appendix

A.1 Actors

There are three types of actors that use MyTaxiService:

- visitors: they can only log in or sign up
- passengers: they can request, reserve or share a taxi
- taxi drivers: they can accept/deny a ride

A.2 Identifying stakeholders

The main stakeholder of the project is the government of a large city. The government, with the help of the transport council, decided to improve the actual taxi service with MyTaxiService. With MyTaxiService the stakeholders want to:

- symplify the access of passangers to the service
- guarantee a fair management of taxi queues
- give the possibility to the passengers to reserve a taxi
- give the possibility to a passenger to share a taxi with other passengers

A.3 Alloy

Here the Alloy code for create MyTaxiService model
